Abstract:
Background: Methillin-resistant Staphylococcus aureus (MRSA), Staphylococcus aureus and Vancomycin-resistant Enterococci (VRE) are capable of surviving for days to weeks on environmental surfaces. Some healthcare facilities have implemented the use of disposable blood pressure cuffs in an effort to prevent cross-contamination of multiple drug resistant organisms, which can add substantial costs. A prospective study was conducted in June 2008 to evaluate the level of bacterial contamination on 30 BP cuffs and 8 pneumatic tourniquet cuffs used in surgical procedures that require the temporary occlusion of blood flow in the extremity. An infection control measure was implemented to disinfect the equipment with an quaternary/isopropyl alcohol germicidal surface cloth.

Objective: To evaluate the effectiveness of a surface cleaning technique followed the post-communication of BP cuffs and tourniquets prior to each patient use.

National Guidelines:
AMA and SHEA Guidelines – JAMA Vol. 280 No. 6, August 12, 1998

The American Medical Association has passed a resolution recommending the cleaning of stethoscopes and other handheld instruments. We support that resolution and suggest the following ways to implement this practice in healthcare settings, including outpatient and home care settings.

1. Wipe the bell, diaphragm, and tubing of stethoscopes and the surface of otoscopes with alcohol swabs between patient uses.
2. Wash hands thoroughly with soap and running water between patient contacts.
3. Have alcohol swabs readily available (e.g., adjacent to sinks, in patient waiting rooms, and at nursing stations). Swabs need to be easily accessible to encourage use.
4. Provide a dedicated stethoscope and other handheld instruments (including blood pressure cuffs) for patients who require contact precautions (e.g., patients isolated because of multiresistant microorganisms, non-compliance with isolation precautions).

Disinfect noncritical medical devices (e.g., blood pressure cuff) with an EPA-registered hospital disinfectant using the label’s safety precautions and use directions. Most EPA-registered hospital disinfectants have a label contact time of 10 minutes. However, multiple scientific studies have demonstrated the efficacy of hospital disinfectants against pathogens with a contact time of at least 1 minute.

Methods: Contact plates were applied to the center portion of the BP cuff and pneumatic tourniquet that touches the patient’s skin during use. The body forming units (cfu) were recorded, as well as the identification of the microorganisms that were found on the equipment.

Conclusions: A surface cleaning with germicidal cloths that are active against Staphylococcus aureus, MRSA and VRE on non-disposable BP cuffs and pneumatic tourniquets appears sufficient to reduce contamination to safe levels between patient use. The cleaning procedure should be done just before each use to prevent cross contamination from shared equipment.

Discussion: Significant bacterial colonization may occur on surfaces of nondisposable blood-pressure cuffs. Contamination of blood-pressure cuffs can be particularly problematic in intensive care units and operating rooms, where the cuffs are commonly exposed to blood and other bodily fluids, thus making the cuffs a possible source of infection if reused. With the increasing recognition that contamination of blood-pressure cuff can be a source of infection, it has been recommended that, where possible, a sterilized cuff, or an unused disposable cuff, be dedicated to each patient upon arrival at a hospital and that the cuff follow the patient around in the hospital. However, dedicating a cuff to each patient requires a large number of cuffs, thereby making the practice expensive. Moreover, it is procedurally difficult to insure that the cuff follows the patient’s movements in the hospital. Disposable cuffs are available as a possible solution, but disposable cuffs also lead to substantial additional expense. Consequently, hospital staff should wipe disposable cuffs on different patients without cleaning the cuffs between patients. This small scale study was undertaken to evaluate the effectiveness of an infection prevention measure to have staff perform surface cleaning BP cuffs with germicidal wipe before each patient use. Results indicate low levels of exogenous contamination on the cuffs and no multiple drug resistant microorganisms.
